

# Lab 49 Worksheet — System Restore, Backup

## Verification and Recovery Testing

Name: \_\_\_\_ Date: \_\_\_\_

**Exam objective:** Configure System Restore and Windows backup, then verify recovery by performing an actual restore (Core 2 objectives 3.1 and 4.3).

### Record as you go

| Step | What you did                                                                                                                                                                     | What you observed |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 1    | Check whether System Protection is enabled on the system drive, since a machine with it disabled has no restore points to fall back on.                                          |                   |
| 2    | Create a restore point manually and confirm it appears in the list, recording its creation time and description.                                                                 |                   |
| 3    | Record what a restore point contains — system files, drivers, registry and installed programs — and what it excludes, which is personal data.                                    |                   |
| 4    | Record when System Restore is the right tool: after a bad driver, a failed update or a software installation that broke the system, but never for recovering a deleted document. |                   |
| 5    | Configure File History or Windows Backup to a separate volume, and record why backing up to the same physical disk protects against nothing but accidental deletion.             |                   |
| 6    | Record the 3-2-1 rule: three copies of the data, on two different media, with one copy off site — and state which threat each part of the rule defeats.                          |                   |
| 7    | Compare the backup types: full copies everything, incremental copies changes since the last backup of any type and clears the                                                    |                   |

| Step | What you did                                                                                                                                                                                           | What you observed |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
|      | archive bit, and differential copies changes since the last full backup and leaves the archive bit set.                                                                                                |                   |
| 8    | Work the restore arithmetic: from a Sunday full backup, restoring Thursday's data needs the full plus four incrementals, but only the full plus one differential — record why this decides the choice. |                   |
| 9    | Move to the Killercoda playground and create a data set with a known checksum so the restore can be verified objectively.                                                                              |                   |
| 10   | Create the backup archive and confirm it exists with a sensible size.                                                                                                                                  |                   |
| 11   | Simulate the data loss by deleting the original directory, then restore from the archive.                                                                                                              |                   |
| 12   | Verify the restore objectively by re-checking the checksums against the originals, which is the step that actually proves the backup worked.                                                           |                   |

## Verification

**Success criterion:** A restore point is created and listed; the archive is created and the original data deleted; the restore returns both files; md5sum -c reports OK for every file; and your recovery procedure states the 3-2-1 rule with the threat each part defeats.

- I completed every step in the lab.
- My result meets the success criterion above.
- I recorded my evidence (screenshots, output, completed tables).

## Reflection

**What surprised you in this lab?**

---

**Where would you apply this on the job?**

---

**What do you still need to revise before the exam?**

---
